

The porous surface of AirNettress provides for urine permeation and creation of a dry surface devoid of urine

Two significant factors in urine induced dermatitis are wetness which leads to excessive hydration and skin maceration with loss of barrier function and skin irritation by contact with urine.

The porous netting of AirNettress facilitates urine permeation and allows for constant aeration thus, creating a dry surface, devoid of urine on which the baby/toddler sleeps. The dry environment and lack of contact with urine significantly reduce the risk factors for skin irritation and dermatitis.
